1. Reddit account connection

First, you need to create a Reddit account and go to this link:
https://www.reddit.com/prefs/apps to create an application. The next optional step is
OAuth2 authorization (doing this will increase the speed of data fetching). The final step
is to obtain the keys to connect to Reddit. You will need the client_id, client_secret, and
user_agent. You can find the client_id and client_secret in the "apps" section of your
project, and the user_agent will be a combination: {project_name} by u/{user} (replace
the curly braces with your details and remove the braces).

2. Insert your client_id, client_secret and user_agent in keys_reddit.py

The simplest way to insert your data into the keys_reddit.py file is by opening it as a .txt file,
adding your data, and then saving the changes.

3. To run the app, make sure that in the same folder as reddit_sentiment_analysis.py, you
    also have the keys_reddit.py file and a folder named Data (which will be empty initially).

4. Open the Reddit_sentiment_analysis.py file in Python. Upon the first run, the application
    will automatically download the required libraries. However, if any issues arise and the
    code fails to run due to missing libraries, you can manually download them.
